area on Earth

Discussion Summary

In this study, it was demonstrated that remote sensing data such as ESRI Land Cover, ESA WorldCover, and Dynamic World all have certain aspects of land cover that they over or under exaggerate, along with aspects that they consistently miss. For example, Dynamic World and ESRI Land Cover all massively underestimated tree cover data, while overestimating the portion of built up areas. Dynamic world, however, was better at capturing the presence of water in the grid, as while it portrayed certain parts of the bayou, ESRI Land Cover completely missed it and portrayed it as a built up area. ESA Worldcover was quite different from the other two, as it heavily over exaggerated tree cover while rarely portraying built up areas—It would only portray an area as built up if it was a large, empty area, such as a parking lot or large building. Like ESRI Land Cover, it completely missed the bayou, though it portrayed it as tree cover rather than a built-up area.

Conclusions | Recommendations

This project illustrated that while satellite and remote sensing data are accurate for large-scale averages and general environmental insights, they often fail to capture finer details and may over exaggerate certain aspects of land cover, leading to the conclusion that while remote sensing data is incredibly useful in making close estimates about information regarding land cover and similar features, real-time field observations are much more accurate on the small scale.

Community Chronicles Background

Houston, especially in the suburbs surrounding the city, has had an increasing amount of construction and housing development within the past few decades, which has drastically lowered the number of grassy fields and open areas throughout the city.

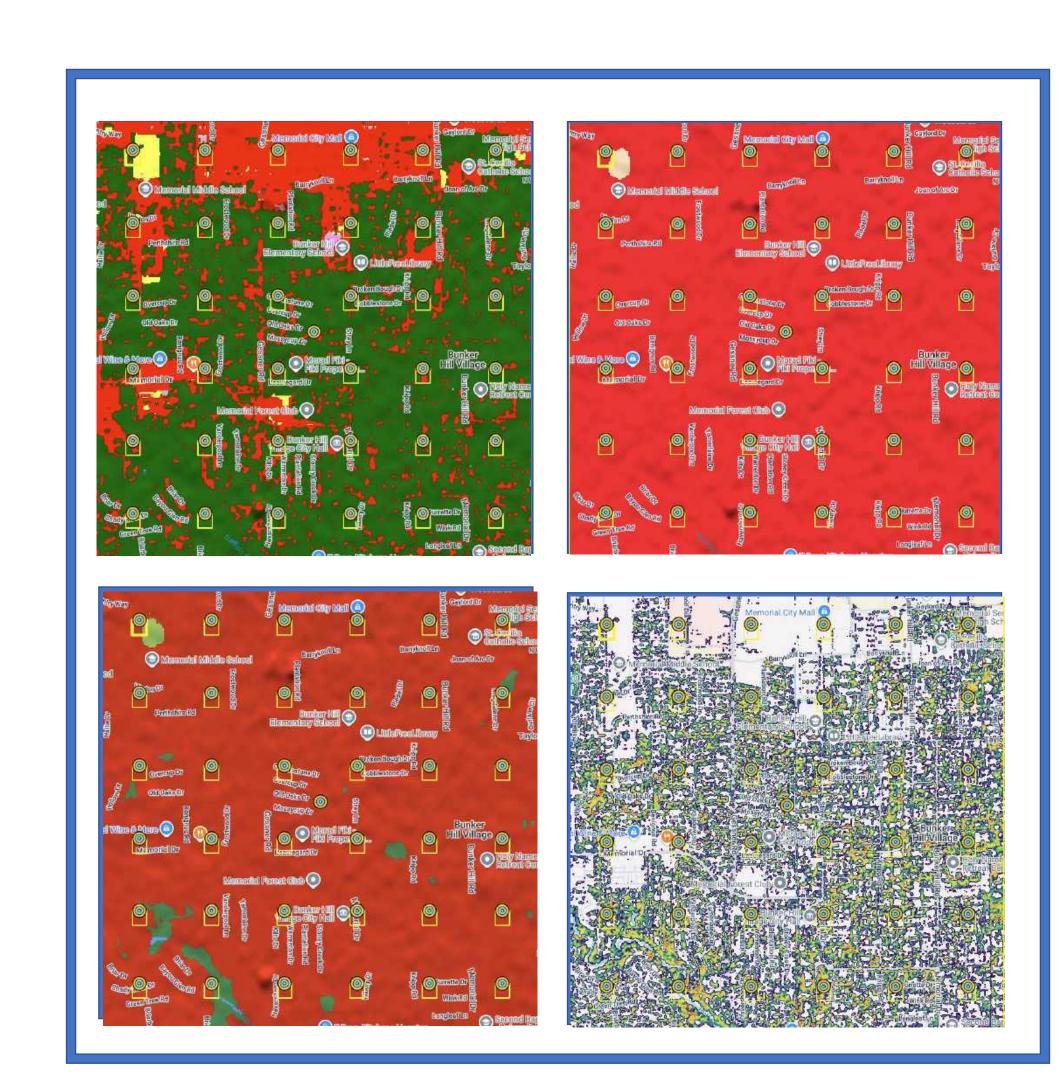

Descriptive statistics

of 37 points, 3 of them (the center, #29, and #30) were inaccessible and therefore data wasn't retrievable. Of these 37 points, 32 of them were dominated by tree cover, with the remainder being almost entirely built-up areas. Though multiple points contained a decent amount of water, only point 12 contained a sizeable portion, up to 50% of the 100x100 meter point was

I wonder how well remote sensing data captures information when compared to on-site observations.

Result Summary

This study evaluated the accuracy of remote sensing datasets—including ESRI Land Cover, ESA WorldCover, and Dynamic World—against field observations, revealing significant discrepancies. While these datasets effectively capture broad land cover trends, each exhibited consistent limitations when compared to ground-level data. For example, both ESRI and Dynamic World substantially underestimated tree cover while overestimating built-up areas. In contrast, ESA WorldCover tended to overrepresent tree cover and often missed smaller built environments unless they were large and unobstructed. Dynamic World proved more reliable in identifying water bodies, such as sections of the bayou, which ESRI and ESA completely misclassified. These findings underscore that while remote sensing tools are invaluable for large-scale environmental monitoring, they may inaccurately represent finer land cover details. Consequently, for localized or high-resolution analyses, field observations remain critical to ensuring precision.
